## Statistical Modeling

CH. 1 - Simple Linear Regression
2023 || Prof. Dr. Buchwitz

## Outline

# 1 Organizational Information 

## 2 Introduction

## 3 Simple Linear Regression

## Contact details

## Lecturer

## Professor Benjamin Buchwitz

- Room 2.3.14, Lindenstr. 53, Meschede

■ Email: Buchwitz.Benjamin@fh-swf.de

## Unit objectives

1. To obtain an understanding of common statistical methods used in statistical modeling.
2 To develop the computer skills required to model relationships found in business, economic and social sciences contexts;
${ }^{3}$ To gain insights into the problems of implementing and conducting analyses for professional use.

## Course Contents

| Session | Topic |
| :--- | :--- |
| 1 | Simple Linear Regression |
| 2 | Multiple Linear Regression |
| 3 | Regression Diagnostics |
| 4 | Qualitative Variables as Predictors |
| 5 | Transformation of Variables |
| 6 | Weighted Least Squares |
| 7 | Correlated Errors |
| 8 | Analysis of Collinear Data |
| 9 | Working with Collinear Data |
| 10 | Variable Selection Procedures |
| 11 | Logistic Regression |
| 12 | Further Topics |

## Examination Modalities

Grading is based on a portfolio examination with three parts:
1 One Lecture Recap Presentation (20\%)
2 Hand-in Exercises (40\%)
3 Final Case Study (40\%)
Outdated!

## Outline

## 1. Organizational Information

2 Introduction
3 Simple Linear Regression

## What is Regression Analysis?

- Regression analysis is a conceptually simple method for investigating functional relationships among variables.
- The relationship is expressed in the form of an equation or a model connecting the response or dependent variable with one ore more explanatory or predictor variabes.
- We denote the response variable by $Y$ and the set of predictor variables by $X_{1}, X_{2}, \ldots, X_{p}$, where $p$ denotes the number of predictor variables.
■ The true relationship between the response and its predictors can be approximated by the regression model, where $\epsilon$ represents the random discrepancy in the relation.

$$
Y=f\left(X_{1}, X_{2}, \ldots, X_{p}\right)+\epsilon
$$

## The Regression Formula

- The function $f\left(X_{1}, X_{2}, \ldots, X_{p}\right)$ describes the relationship between $Y$ and $X_{1}, X_{2}, \ldots, X_{p}$ and can take any functional form.
■ One example of a function is the linear regression model:

$$
Y=\beta_{0}+\beta_{1} X_{1}+\beta_{2} X_{2}+\ldots \beta_{p} X_{p}+\epsilon
$$

- Here $\beta_{0}, \beta_{1}, \ldots, \beta_{p}$ are called the regression parameters or coefficients, which are unknown constants and need to be estimated from data.

## Data Example: River Data

■ Nitrogen: Mean nitrogen concentration ( $\mathrm{mg} / \mathrm{I}$ ) based on samples taken at regular intervals during the spring, summer and fall months
■ Agr: Percentage of land area currently in agricultural use

- Forest: Percentage of forest land

■ Rsdntial: Percentage of land area in residential use
■ ComIndl: Percentage of land area in either commercial or industrial use

```
head(P010)
```

| \#\# | Agr | Forest | Rsdntial | ComIndl | Nitrogen |
| :--- | ---: | ---: | ---: | ---: | ---: |
| \#\# Olean | 26 | 63 | 1.2 | 0.29 | 1.10 |

## Steps in Regression Analysis

1 Statement of the problem
2 Selection of potentially relevant variables
3 Data collection
4. Model specification

5 Choice of fitting method
6 Model fitting
7 Model validation and criticism
8 Using the chosen model(s) for the solution of the proposed problem

## Statement of the problem

■ Every analysis starts with the definition of the problem, which includes formulation of questions adressed by the analysis.

- III-defined problems or misformulated questions can lead to wasted effort or the selection of a wrong model.
- Finding and formulating suitable questions is probably the hardest part in an analysis.

## Example: Problem Statement Definition

■ Assume we want to research whether or not an employer is discriminating against a group of employees, e.g. women and data on salary, gender and qualification is available.

- There are multiple definitions of discriminations available in the literature (a) women are paid less than equally qualified men, or (b) women are more qualified than equally paid men.

## Example: Problem Statement Definition

- Assume we want to research whether or not an employer is discriminating against a group of employees, e.g. women and data on salary, gender and qualification is available.
- There are multiple definitions of discriminations available in the literature (a) women are paid less than equally qualified men, or (b) women are more qualified than equally paid men.

## Your turn

What is the modeling implication of the definition?

## Example: Problem Statement Definition

- Assume we want to research whether or not an employer is discriminating against a group of employees, e.g. women and data on salary, gender and qualification is available.
- There are multiple definitions of discriminations available in the literature (a) women are paid less than equally qualified men, or (b) women are more qualified than equally paid men.

## Your turn

What is the modeling implication of the definition?
a) salary $=f(q u a l i f i c a t i o n, ~ g e n d e r) ~+\epsilon$
b) qualification $=f($ salary, gender $)+\epsilon$

## Outline

## 1 Organizational Information

## 2 Introduction

3 Simple Linear Regression

## Introduction

$$
Y=f(X)+\epsilon
$$

- We start with the simple case to study the relationship between the response $Y$ and a single predictor $X$.
■ As we only have one regressor variable we drop the subscript to simplify the notation $\left(X_{1}=X\right)$.
- We derive and formulate the regression model and focus on the key results but favor numerical examples over mathematical derivations.

## Covariance

## Covariance

## Determine the sign:

$\square y_{i}-\bar{y}$ the deviation of each observation $y_{i}$ from the mean of the response variable,
$\square x_{i}-\bar{x}$ the deviation of each observation $x_{i}$ from the mean of the predictor variable, and
■ the product of the above quantities, $\left(y_{i}-\bar{y}\right)\left(x_{i}-\bar{x}\right)$

| Quadrant | $y_{i}-\bar{y}$ | $x_{i}-\bar{x}$ | $\left(y_{i}-\bar{y}\right)\left(x_{i}-\bar{x}\right)$ |
| :--- | :--- | :--- | :--- |
| 1 (top right) |  |  |  |
| 2 (top left) |  |  |  |
| 3 (bottom left |  |  |  |
| 4 (bottom right) |  |  |  |

## Covariance

## Positive Relationship

- If the linear realtionship between $Y$ and $X$ is positive (when $X$ increases, $Y$ also increases), then there are more points in the first and third quadrants than in the second and fourth.
- The sum over the elements in the last column is likely to be positive, that is $\operatorname{Cov}(Y, X)>0$.

## Covariance

## Positive Relationship

- If the linear realtionship between $Y$ and $X$ is positive (when $X$ increases, $Y$ also increases), then there are more points in the first and third quadrants than in the second and fourth.
- The sum over the elements in the last column is likely to be positive, that is $\operatorname{Cov}(Y, X)>0$.

## Negative Relationship

- If the linear relationship between $Y$ and $X$ is negative (as $X$ increases $Y$ decreases), then there are more points in the second and fourth quadrants than in the first and third.
- The sum over the elements in the last column is likely to be negative, that is $\operatorname{Cov}(Y, X)<0$.

## Covariance

$$
\operatorname{Cov}(X, Y)=\frac{1}{n-1} \sum_{i=1}^{n}\left(y_{i}-\bar{y}\right)\left(x_{i}-\bar{x}\right)
$$

- The quantity calculated using the above formula is called the covariance.
- The sign of the covariance indicates the relationship between $Y$ and $X$.
- The covariance can only indicate the direction of a relationship, and does not tell much about the strength of the relationship.
- the covariance is unit sensitive, changing the unit of a measurement (e.g. from Euro to kEuro) changes the value of the covariance.

## Your turn

What happens if we calculate $\operatorname{Cov}(X, Y)$ instead of $\operatorname{Cov}(Y, X)$ ?

## Correlation Coefficient

- To avoid the obvious disadvantages of the covariance we can standardize (z-transform) each variable before computing the covariance.
■ Standardizing $Y$ means subtracting the mean $\bar{y}$ and dividing by the associated sample standard deviation $s_{y}$.
■ The resulting variable $z_{i}$ has mean zero and unit standard deviation.

$$
z_{i}=\frac{y_{i}-\bar{y}}{s_{y}} \quad \text { with } \quad s_{y}=\sqrt{\frac{\sum_{i=1}^{n}\left(y_{i}-\bar{y}\right)^{2}}{n-1}}
$$

## Correlation Coefficient

$$
\operatorname{Cor}(Y, X)=\frac{1}{n-1} \sum_{i=1}^{n}\left(\frac{y_{i}-\bar{y}}{s_{y}}\right)\left(\frac{x_{i}-\bar{x}}{s_{X}}\right)=\frac{\operatorname{Cov}(Y, X)}{s_{y} s_{X}}
$$

- Calculating the covariance of the standardized values yields the correlation coefficient.
- $\operatorname{Cor}(Y, X)$ can be interpreted in two ways, either as
- the covariance between two standardized variables or as
- the ratio of the covariance to the standard deviations of the two variables
- Opposed to the covariance, $\operatorname{Cor}(Y, X)$ is scale invariant so that it is not affected by unit changes. It also satisfies $-1 \geq \operatorname{Cor}(Y, X) \leq 1$ and therefore indicates direction and strength.

## Correlation Coefficient

$\operatorname{Cor}(Y, X)=0$ does not necessarily mean that the variables are not related!

```
x <- seq(from=-5, to=5,by=.1)
y <- 50 - x^2
cor_yx = cor(y,x)
round(cor_yx, digits=4)
```

\#\# [1] 0
plot ( $x, y$ )

## Example: Anscombe Quartet

```
knitr::kable(anscombe[,c("y1","x1","y2","x2","y3","x3","y4","x4")], booktabs=T)
```

| y 1 | x 1 | y 2 | x 2 | y 3 | x 3 | y 4 | x 4 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 8.04 | 10 | 9.14 | 10 | 7.46 | 10 | 6.58 | 8 |
| 6.95 | 8 | 8.14 | 8 | 6.77 | 8 | 5.76 | 8 |
| 7.58 | 13 | 8.74 | 13 | 12.74 | 13 | 7.71 | 8 |
| 8.81 | 9 | 8.77 | 9 | 7.11 | 9 | 8.84 | 8 |
| 8.33 | 11 | 9.26 | 11 | 7.81 | 11 | 8.47 | 8 |
| 9.96 | 14 | 8.10 | 14 | 8.84 | 14 | 7.04 | 8 |
| 7.24 | 6 | 6.13 | 6 | 6.08 | 6 | 5.25 | 8 |
| 4.26 | 4 | 3.10 | 4 | 5.39 | 4 | 12.50 | 19 |
| 10.84 | 12 | 9.13 | 12 | 8.15 | 12 | 5.56 | 8 |
| 4.82 | 7 | 7.26 | 7 | 6.42 | 7 | 7.91 | 8 |
| 5.68 | 5 | 4.74 | 5 | 5.73 | 5 | 6.89 | 8 |

## Your turn

Choose one of the datasets (e.g. $i=3$ ) and calculate $\overline{y_{i}}, \overline{x_{i}}, \operatorname{Cov}\left(y_{i}, x_{i}\right)$ and $\operatorname{Cor}\left(y_{i}, x_{i}\right)$ using R (Hint: mean, cov, cor).

## Results: Anscombe Quartet

## Learning: Anscombe Quartet

- Like many other summary statistics the correlation coefficient can be substantially influenced by one of a few outliers in the data.
- All four datasets in the Anscombe quartet have almost the same summary statistics, despite being inherently different.
- A purely descriptive analysis can not reveal the different patterns we need to plot the data before starting an analysis.
- Findings:
a) can be adequately described by a linear model
b) is nonlinear and would be better fitted by a quadratic function
c) one outlier distorts the slope and intercept of the lines
d) is unsuitable for linear fitting as the line is determined by a single extreme observation

## Example: Computer Repair Data

```
# Minutes = Duration of the service operation
# Units = Number of computers repaired during service operation
head(P031)
```

\#\# Minutes Units
\#\# $1 \quad 23 \quad 1$
\#\# 292
\#\# 34
\#\# $4 \quad 64$
\#\# $5 \quad 74$
\#\# 67

## Your turn

Calculate $\operatorname{Cov}(Y, X)$ and $\operatorname{Cor}(Y, X)$ manually (step-by-step) using R by avoiding the internal functions cov and cor.

## The Simple Linear Regression Model

- The correlation coefficient is useful to measure the strength of a pairwise relationship, it cannot be used for prediction purposes.
- That means that we cannot use $\operatorname{Cor}(Y, X)$ to predict one variable, when the other one is given.
- Regression is an extension to correlation analysis and cannot only measure direction, but allows for numerically describing that relationship.

## The Simple Linear Regression Model

$$
Y=\beta_{0}+\beta_{1} X+\epsilon
$$

- $\beta_{0}$ and $\beta_{1}$ are constants called the regression coefficients, and $\epsilon$ is the error term.
- $\beta_{0}$ is called the intercept. It is the prediction value, when $X=0$.
- $\beta_{1}$ is called the slope. It can be interpreted as the change in $Y$, when $X$ changes by one unit.
- Each observation in the data can therefore be written as:

$$
y_{i}=\beta_{0}+\beta_{1} x_{i}+\epsilon_{i} \quad \text { with } \quad i=1,2, \ldots, n
$$

## The Simple Linear Regression Model

- We assume that (in the range of our observations studied), the linear equation provides an acceptable approximation to the real relationship: $Y$ is approximately a linear function of $X$.
- The error term $\epsilon$ measures the discrepancy of the approximation.
- That simple linear regression model is linear in two ways:
- the relationship between $X$ and $Y$ is linear
- more generally the word linear describes that the regression parameters $\beta_{0}$ and $\beta_{1}$ enter the equation in a linear fashion
- $Y=\beta_{0}+\beta_{1} X^{2}+\epsilon$ is still a linear model but with a quadratic term!
- In correlation $X$ and $Y$ are of equal "importance" which is reflected in the symmetry $\operatorname{Cor}(Y, X)=\operatorname{Cor}(X, Y)$.
■ In regression we want to explain $Y$, hence the importance of the predictor $X$ lies on its ability to account for the variability of the response.

## Example: Computer Repair Data

Reconsidering the computer repair data and assuming we want to predict the numbers of support engineers that will be required for a task, we can now formulate an equation in form of a linear model that is assumed to represent the relationship between the length of service calls and the number of electronic components in the computer that must be repaired.

$$
\text { Minutes }=\beta_{0}+\beta_{1} \text { Units }+\epsilon
$$

## Your turn

Consult the scatter plot (plot) of the data (P031) and check whether the straight linear relationship is a reasonable assumption.

Parameter Estimation

## How do we

## determine $\beta_{0}$ and $\beta_{1}$ ?

## Parameter Estimation

plot(P031\$Minutes,P031\$Units,xlab="Minutes", ylab="Units", pch=19)

## Parameter Estimation

- We want values for $\beta_{0}$ and $\beta_{1}$ that give the best fit or the best representation for the points in the graph.
- This can be achieved using the least squares method that minimizes the sum of squares of vertical distances.
- Those vertical distances from each point to the line represent the errors $\epsilon_{i}$ and can be obtained by:

$$
\epsilon_{i}=y_{i}-\beta_{0}-\beta_{1} x_{1} \quad \text { for } \quad i=1,2, \ldots, n
$$

## Parameter Estimation

- As $\beta_{0}$ and $\beta_{1}$ are unknown, but required to calculate the errors and therefore the sum of squared errors, we can devise a function for that:

$$
S\left(\beta_{0}, \beta_{1}\right)=\sum_{i=1}^{n} \epsilon_{i}^{2}=\sum_{i=1}^{n}\left(y_{i}-\beta_{0}-\beta_{1} x_{1}\right)^{2}
$$

- This is a quadratic function that can be minimized. The analytical solution for the values $\hat{\beta}_{0}$ and $\hat{\beta}_{1}$ that minimize the function $S()$ are

$$
\hat{\beta}_{1}=\frac{\sum\left(y_{i}-\bar{y}\right)\left(x_{i}-\bar{x}\right)}{\sum\left(x_{i}-\bar{x}\right)^{2}} \quad \text { and } \quad \hat{\beta}_{0}=\bar{y}-\hat{\beta}_{1} \bar{x}
$$

- Both, $\hat{\beta}_{0}$ and $\hat{\beta}_{1}$ are called the least squares estimates and give the line with the smallest possible sum of squares of vertical distances.

## Parameter Estimation

■ The least squares regression line can always be found (does always exist) and is given by

$$
\hat{Y}=\hat{\beta}_{0}+\hat{\beta}_{1} X
$$

■ For each observation we can compute a fitted value, which is given by

$$
\hat{y}_{i}=\hat{\beta}_{0}+\hat{\beta}_{1} x_{i} \text { for } i=1,2 \ldots, n
$$

■ Each point $\left(x_{i}, \hat{y}_{i}\right)$ is a point on the regression line

- The corresponding vertical distances are called ordinary least squares residuals an can be computed like

$$
\hat{\epsilon}_{i}=y_{i}-\hat{y}_{i} \text { for } i=1,2 \ldots, n
$$

## Parameter Estimation

## Your turn

Add a sketch of the least squares regression line to the plot above and include, mark and annotate the fitted values and the ordinary least squares residuals.

## Parameter Estimation

## Parameter Estimation

## Your turn

- Calculate $\hat{\beta}_{0}$ and $\hat{\beta}_{1}$ twice using R.

1) Manually (abstain from cor and cov) using $R$
2) Using the functions mentioned above

- Plot the data and add your calculated regression line to that plot (Hint: abline)

## Tests of Hypotheses

- So far we only made one assumption or hypothesis about the relationship between the response and predictor variables, which is called the linearity assumption.
■ An early step in an analysis should always be the validation of this assumption: We wish to determine if the data at hand supports the assumption that $Y$ and $X$ are linearly related.
- An informal way to check this assumption is to check the scatter plot.
- A more formal way to check the assumption and to measure the usefulness of $X$ as a predictor for $Y$ is to conduct a hypothesis test about the regression parameter $\beta_{1}$.

## Tests of Hypotheses

■ Testing for the postulated relationship can be done by checking the hypothesis that $\beta_{1}=0$, which means that there is no linear relationship between $X$ and $Y$.

- Finding that $\beta_{1}>0$ or $\beta_{1}<0$ is equivalent to $\beta_{1} \neq 0$ and would provide evidence (not proof!) for an existing linear relationship.
- Testing of this hypothesis requires the assumption that the errors $\epsilon_{i}$ are independent random quantitites originating from a normal distribution with zero mean and common variance $\sigma^{2}$.
- $\epsilon \sim N\left(0, \sigma^{2}\right)$
- $\epsilon_{i}$ are independent

## Tests of Hypotheses

- Given that the assumptions for the error term $\epsilon$ hold, $\hat{\beta}_{0}$ and $\hat{\beta}_{1}$ are unbiased estimates of $\beta_{0}$ and $\beta_{1}$.
- This means that $\hat{\beta}_{0}$ and $\hat{\beta}_{1}$ allow to draw conclusions about the unobserved and unknown parameters $\beta_{0}$ and $\beta_{1}$ in the population, hence $\boldsymbol{E}(\hat{\beta})=\beta$.
- Under the mentioned circumstances the variances of the regression coefficients are

$$
\operatorname{Var}\left(\hat{\beta}_{0}\right)=\sigma^{2}\left[\frac{1}{n}+\frac{\bar{x}^{2}}{\sum\left(x_{i}-\bar{x}\right)^{2}}\right] \quad \text { and } \quad \operatorname{Var}\left(\hat{\beta}_{1}\right)=\frac{\sigma^{2}}{\sum\left(x_{i}-\bar{x}\right)^{2}}
$$

- The variances of $\hat{\beta}_{0}$ and $\hat{\beta}_{1}$ depend on the unknown and unobservable parameter $\sigma^{2}$, which needs to be estimated from the data before we can proceed.

## Tests of Hypotheses

- An unbiased estimate of $\sigma^{2}$ is given by

$$
\hat{\sigma}^{2}=\frac{\sum \epsilon_{i}^{2}}{n-2}=\frac{\sum\left(y_{i}-\hat{y}_{i}\right)^{2}}{n-2}=\frac{S S E}{n-2}
$$

- Here SSE is an abbreviation for Sum of Squares Error (Residuals).
- The number $n-2$ is called degrees of freedom (df) and is equal to the number of observations $n$ minus the number of esimated regression coefficients.

## Tests of Hypotheses

- Plugging $\hat{\sigma}^{2}$ into $\operatorname{Var}\left(\hat{\beta}_{0}\right)$ and $\operatorname{Var}\left(\widehat{\beta}_{1}\right)$ yields unbiased estimates of the respective variances.
- The estimate of the standard deviation is called the standard error (s.e.)

$$
\text { s.e. }\left(\hat{\beta}_{0}\right)=\hat{\sigma}^{2} \sqrt{\frac{1}{n}+\frac{\bar{x}^{2}}{\sum\left(x_{i}-\bar{x}\right)^{2}}} \text { and s.e. }\left(\hat{\beta}_{1}\right)=\frac{\hat{\sigma}^{2}}{\sqrt{\sum\left(x_{i}-\bar{x}\right)^{2}}}
$$

- The standard error of $\hat{\beta}_{1}$ is a measure of how precisely the slope has been estimated. The smaller s.e. $\left(\hat{\beta}_{1}\right)$, the more precise is the estimator.

## Tests of Hypotheses

We are now in the position to perform statistical analysis concerning the usefulness of $X$ as a predictor of $Y$. Under the assumption of normality, an appropriate test for testing the hypothesis is the $t$-test.

$$
H_{0}: \beta_{1}=0 \text { versus } H_{1}: \beta_{1} \neq 0
$$

The test statistic follows a Student t distribution with $n-2$ degress of freedom and we need a specified significance value (e.g. $\alpha=0.05$ ) to perform the test.

$$
t_{1}=\frac{\hat{\beta}_{1}}{\text { s.e. }\left(\hat{\beta}_{1}\right)}
$$

## Tests of Hypotheses

Carrying out the test is done by comparing the value $t_{1}$ against the appropriate critical value obtained from the t -table, which is $\mathrm{t}_{(n-2, \alpha / 2)}$ (Note that we devide $\alpha$ by 2 as we have a two-sided test).

## Reject $H_{0}$ at the given significance level if:

$$
t_{1} \geq t_{(n-2, \alpha / 2)} \quad \text { or } \quad t_{1} \leq-t_{(n-2, \alpha / 2)}
$$

One condition is fulfilled if $\left|t_{1}\right| \leq t_{(n-2, \alpha / 2)}$. A criterion equivalent to that is to compare the p -value (implicit probability value) for the t -test with $\alpha$ and reject $H_{0}$ if $p\left(\left|t_{1}\right|\right) \leq \alpha$, where $p\left(\left|t_{1}\right|\right)$, called the $p$-value, is the sum of the two shaded areas under the following curve. This value is also provided by $R$.

## Tests of Hypotheses

## Tests of Hypotheses

The $t$-test can be generalized to test the more general hypothesis $H_{0}: \beta_{1}=\beta_{1}^{0}$, where $\beta_{1}^{0}$ is a constant chosen by the data analyst.

$$
t_{1}=\frac{\hat{\beta}_{1}-\beta_{1}^{0}}{\text { s.e. }\left(\hat{\beta}_{1}\right)}
$$

The t -test can also be used for testing the intercept $\beta_{0}$ in the same fashion.

## Confidence Intervals

Based on the assumption that the errors $\epsilon$ are normally distributed $\epsilon \sim N\left(0, \sigma^{2}\right)$, we concluded that the sampling distribution of $\beta_{0}$ and $\beta_{1}$ is also normal.

■ The $(1-\alpha) \cdot 100 \%$ confidence intervals for $\beta_{0}$ and $\beta_{1}$ are given by

$$
\hat{\beta}_{0} \pm t_{(n-2, \alpha / 2)} \cdot \text { s.e. }\left(\hat{\beta}_{0}\right) \quad \text { and } \quad \hat{\beta}_{1} \pm t_{(n-2, \alpha / 2)} \cdot \text { s.e. }\left(\hat{\beta}_{1}\right)
$$

- with $t_{(n-2, \alpha / 2)}$ being the $(1-\alpha / 2)$ percentile of a $t$ distribution with $n-2$ degrees of freedom
- Interpretation: If we took repeated samples of the same size ( $n$ ) at the same values of $X$ and construct e.g. the $95 \%$ confidence intervals for the slope parameter (based on $\hat{\beta}_{1}$ ) for each sample, then $95 \%$ of these intervals would be expected to contain the true but unknown value $\beta_{1}$ of the slope.

## Predictions

In addition to describing and explaining observed relationships, the fitted regression equation can be used for prediction. We distinguish two types of predictions:

1) The prediction of the value of the response Variable $Y$ which corresponds to any chosen value $x_{0}$ of the predictor variable.
(2) The estimation of the mean response $\mu_{0}$, when $X=x_{0}$.

## Predictions

## Value of Response \& Prediction Limits

The predicted value $\hat{y}_{0}$ is given by $\hat{y}_{0}=\hat{\beta}_{0}+\hat{\beta}_{1} x_{0}$. Its confidence interval can be constructed by $\hat{y}_{0} \pm t_{(n-2, \alpha / 2)}$ s.e. $\left(\hat{y}_{0}\right)$. The standard error of the prediction is

$$
\text { s.e. }\left(\hat{y}_{0}\right)=\hat{\sigma} \sqrt{1+\frac{1}{n}+\frac{\left(x_{0}-\bar{x}\right)^{2}}{\sum\left(x_{i}-\bar{x}\right)^{2}}}
$$

## Mean Response \& Confidence Limits

The predicted value $\hat{\mu}_{0}$ is given by $\hat{\mu}_{0}=\hat{\beta}_{0}+\hat{\beta}_{1} x_{0}$. Its confidence interval is given by $\hat{\mu}_{0} \pm t_{(n-2, \alpha / 2)} \cdot$ s.e. $\left(\hat{\mu}_{0}\right)$. The standard error of the prediction is

$$
\text { s.e. }\left(\hat{\mu}_{0}\right)=\hat{\sigma} \sqrt{\frac{1}{n}+\frac{\left(x_{0}-\bar{x}\right)^{2}}{\sum\left(x_{i}-\bar{x}\right)^{2}}}
$$

## Predictions

- How do those two predictions differ from each other?

## Predictions

■ How do those two predictions differ from each other?
■ What do they have in common?

## Predictions

■ How do those two predictions differ from each other?

- What do they have in common?
- Why is the uncertainty smaller when predicting the mean response $\hat{\mu}_{0}$ instead of the single value $\hat{y}_{0}$ ?

## Predictions

## Your turn

Use the computer repair data (P031) to do the following with:

- Predict the length of a service call and the associated standard deviation in which four components have to be repaired
- Estimate the expected mean service time for calls that needed four components to be repaired.

## Predictions

## Your turn

Use the computer repair data (P031) to do the following with:

- Predict the length of a service call and the associated standard deviation in which four components have to be repaired
■ Estimate the expected mean service time for calls that needed four components to be repaired.

There are two dangers in such calculations:
■ Notice the substantial uncertainty / the large standard error
■ The linear relationship may only hold in the range of the observed data. In case of the computer repair data we would for example not use this procedure to predict service times for services which require e.g. 25 components to be repaired

## Goodness of Fit

Which line has a higher quality of fit and therefore resembles the underlying relationship better?

## Goodness of Fit

The quality of the fit can be assessed by one of the following (highly related) ways:
1 The discussed tests (if $H_{0}$ is rejected), the magnitude of the values gives us information about the strength (not only existence) of the linear relationship between $Y$ and $X$. The larger $|t|$ (or the smaller the $p$-value), the stronger the linear relationship. The tests are objective but require the stated assumption of normality of $\epsilon$.
2 One can also revert to $\operatorname{Cor}(Y, X)$ and the scatter plot of the data. The closer the set of points to a straignt line, the closer is $|\operatorname{Cor}(Y, X)|$ to 1 and the stronger is the linear relationship between $Y$ and $X$. This approach is informal and subjective, but requires only the linearity assumption.

## Goodness of Fit

3 Examine the scatter plot of the response $Y$ versus the fitted values $\hat{Y}$. The closer the points to a straight line, the stronger is the linear relationship. This can be measured using the correlation $\operatorname{Cor}(\hat{Y}, Y)$. In simple linear regression this is redundant, as $\operatorname{Cor}(\hat{Y}, Y)=|\operatorname{Cor}(Y, X)|$. However when multiple regressors are available this is an informative plot.
4 Decomposition of the variance $\operatorname{Var}(Y)$, which is in fact closely related to the previous approach of using $\operatorname{Cor}(\hat{Y}, Y)$, but useful for simple and multivariate linear regression.

## Goodness of Fit

After computing the least squares estimates let us compute these quantities.

$$
\begin{aligned}
& S S T=\sum\left(y_{i}-\bar{y}\right)^{2} \\
& S S R=\sum\left(\hat{y}_{i}-\bar{y}\right)^{2} \\
& S S E=\sum\left(y_{i}-\hat{y}_{i}\right)^{2}
\end{aligned}
$$

- Sum of Squares Total (SST) is the total deviation of $Y$ from its mean $\bar{y}$.
- Sum of Squares Regression (SSR) is the explained deviation, that is modeled by the regression line.
■ Sum of Squares Error (SSE) is the total deviation of the residuals.

## Goodness of Fit (Graphical Illustration)

|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| - |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| - |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

## Goodness of Fit

## $S S T=S S R+S S E$

## Goodness of Fit

$$
\begin{aligned}
& S S T=S S R+S S E \\
& y_{i}=\hat{y}_{i}+\left(y_{i}-\hat{y}_{i}\right) \\
& \text { Observed }=\text { Fit }+\quad \text { Deviation from Fit }
\end{aligned}
$$

## Goodness of Fit

$$
\begin{aligned}
S S T & =S S R+\text { SSE } \\
y_{i} & =\hat{y}_{i}+\left(y_{i}-\hat{y}_{i}\right) \\
\text { Observed } & =\text { Fit }+ \text { Deviation from Fit }
\end{aligned}
$$

Subtracting $\bar{y}$ yields:

$$
y_{i}-\bar{y}=\left(\hat{y}_{i}-\bar{y}\right)+\left(y_{i}-\hat{y}_{i}\right)
$$

Deviation from mean $=$ Deviation due to Fit + Residual
The sum of squared deviations in $Y$ can be decomposed accordingly!

## Goodness of Fit

■ The first, SSR, measures the quality of $X$ as a predictor of $Y$
$\square$ the second, SSE, measures the error in this prediciton.

- Therefore the ratio $R^{2}=S S R / S S T$ is the proportion of the total variation in $Y$ that is accounted for by the predictor $X$. It follows that:

$$
R^{2}=\frac{S S R}{S S T}=1-\frac{S S E}{S S T}
$$

## Goodness of Fit

## Your turn

Calculate the $R^{2}$ for the Computer repair data and show that $R^{2}=[\operatorname{Cor}(Y, X)]^{2}=[\operatorname{Cor}(Y, \hat{Y})]^{2}$ holds in the case of simple linear regression.
